What is a Commercial electrolyte for vanadium flow batteries?

Commercial electrolyte for vanadium flow batteries is modified by dilution with sulfuric and phosphoric acid so that series of electrolytes with total vanadium, total sulfate, and phosphate concentrations in the range from 1.4 to 1.7 m, 3.8 to 4.7 m, and 0.05 to 0.1 m, respectively, are prepared.

What is the operating temperature of vanadium redox flow batteries?

Vanadium redox flow batteries (VRFBs) are promising candidates for large-scale energy storage, and the electrolyte plays a critical role in chemical-electrical energy conversion. However, the operating temperature of VRFBs is limited to 10-40 °C because of the stability of the electrolyte.

What happens if the operating temperature of a vanadium battery is high?

If the operating temperature of the vanadium electrolyte is higher than 40 °C or lower than 10 °C, both the electrolyte stability and energy density of vanadium batteries will decrease, accompanied by capacity loss and battery failure .

What is a vanadium redox flow battery (VRFB)?

In the case of Vanadium redox flow batteries (VRFBs), the electrolyte solution containing different valences of vanadium in the anolyte and catholyte is separated by a membrane. Due to their independent power output and energy capacity, VRFBs are easily scalable and therefore suitable for large-scale energy storage applications.
