-----

As a supplier of Phase Shifting Transformers (PSTs), I am often asked whether these specialized transformers can be effectively used in a smart grid. In this blog post, I will explore the ...

Both phase-shifting transformers (PSTs) and advanced power flow control (APFC) exist to influence that behavior. They aim at the same outcome: more usable capacity and more control over ...

Phase shifting transformers are key to creating balance within and between power networks. With their capability to provide active power flow control, phase shifters not only improve the stability and ...

Phase shift transformer (PST) is a special type of transformer that can control power flow in three-phase transmission systems by injecting series voltage whose angle can be controlled.

PST - a specialized type of transformer that controls active power (P) flow in power grid while operating by reliable LTCs and advanced-retard switch (ARS) application.

In high voltage electric grids, phase shifting transformers (PSTs) are devices in which the phase shift across the device can be varied to control the flow of real power.

As an effective power flow control device, the phase shifting transformer (PST) has the advantages of good regulation performance, no change of grid structure, low investment cost, and good application ...

A comprehensive study is carried out for the proper selection of the appropriate phase-shifted transformer to improve power quality and energy efficiency, and to ensure grid reliability and ...
